

Figure 1 is a line graph showing the probability of a tropical cyclone (TC) making landfall within 100 km of a coastal point as a function of lead time (d). The y-axis represents the probability, ranging from 0.0 to 1.0. The x-axis represents lead time in days, ranging from 0 to 9. Three vertical dashed lines indicate key milestones: 'start warnings' at day 2, 'end COS' at day 5, and 'end DWD' at day 6. The graph displays multiple lines representing different TCs. A thick black line shows the highest probability, starting at approximately 0.7 at day 0 and decreasing to about 0.15 at day 9. Several blue lines represent other TCs, with probabilities generally lower than the black line. All lines show a general decrease in probability as lead time increases.
